EXECUTIVE SUMMARY

The high status of teachers is vital to the functioning of schools and to instilling parental confidence in all educational systems. The Varkey Foundation's Global Teacher Status Index (GTSI) survey represents the most comprehensive research that has ever been conducted to robustly document teacher status around the world. The latest survey, which commissioned by the foundation in 2018, collected data on teacher status from a diverse sample of 35 countries, covering Africa, the Americas, Asia, Australasia and Europe. It followed on from a survey commissioned by the Varkey Foundation in 2013 that documented teacher status in 21 countries.

The Global Teacher Status Index is the most comprehensive research ever conducted on the status of the teaching profession around the world.

In our 2018 report that set out the results from the latest GTSI survey, we collated a variety of indicators to derive a single international index of teacher status.¹ We found dramatic variations in teacher status between countries, consistent with the findings from our 2013 survey. We also found that this variation appeared to be substantively related to children's attainment as measured by scores on the 2018 OECD Programme for International Student Assessment (PISA).

Our objectives in the present report are threefold. First, we explore the concept of teacher status more thoroughly than we were able to in the previous omnibus report. Second, we conduct a more robust investigation of the link between teacher status and student attainment (making use of updated PISA data). And third, we explore the factors which may explain why teachers enjoy higher status in some countries than others.

¹ Dolton, Marcenaro, de Vries and She, *Global Teacher Status Index 2018*, Varkey Foundation (2018)

THREE NEW MEASURES OF TEACHER STATUS

Our first task in this report is to more thoroughly explore the concept of ‘teacher status’. Our primary measure of teacher status is the Global Teacher Status Index (GTSI) itself. This measure uses a mathematical technique called Principal Component Analysis to take information from a variety of different survey questions about teachers and summarise it in a single score from 0-100. This score indicates the overall status of teachers in each country under consideration.

The GTSI is a framework that allows us to consider teacher status as a single, unitary concept. However, people’s views of teachers are likely to be more nuanced than a single measure allows. In this report, we explore three alternate ways of assessing people’s views of teacher status. We compare them against each other, and against the GTSI itself. These measures are described in detail in the section “Teacher status: Three alternate measures”. However, briefly, we contrast:

- **Ranked Teacher Status:** A measure based on how teachers are ranked relative to other comparable occupations;
- **Implicit Teacher Status:** A scale based on people’s implicit perceptions of teachers; and
- **Explicit Teacher Status:** A scale based on people’s explicit judgements of teachers’ characteristics and working conditions.

Exploring these varying focuses and measurement approaches allows us to come to a deeper understanding of people’s multifaceted views of teachers. In contrasting these measures, we find that, although they are all linked (again suggesting that we are tapping into a single underlying stance towards teachers), they are nevertheless distinct.

THE RELATIONSHIP BETWEEN TEACHER STATUS AND LEARNING OUTCOMES

The distinction between these three alternative measures is important to our second objective: an analysis of the relationship between teacher status and student learning outcomes. In this analysis we use the latest available PISA data, published in 2018. Our results re-affirm our previous finding that teacher status can be an important predictor of student attainment, as measured by PISA scores in Reading, Mathematics and Science.

In comparing the latest PISA results with the GTSI and our three alternate measures, we find:

- **2018 GTSI:** Teacher status, as measured by the GTSI, is moderately positively correlated with 2018 PISA results. In countries with higher GTSI scores, PISA scores tend to be higher. Around 8% of the variation in PISA scores between countries is explained by differences in teacher status as measured by the GTSI 2018.
- **Ranked Teacher Status:** Again, there is a moderate positive correlation between Ranked Teacher Status and the 2018 PISA results. In countries where teachers are ranked higher in terms of respect relative to other occupations, PISA scores tend to be higher. Around 13% of the variation in PISA scores between countries is explained by differences in teacher status rankings.
- **Implicit Teacher Status:** There is a remarkably strong positive correlation between Implicit Teacher Status and the 2018 PISA results. PISA scores are significantly higher in countries where people implicitly view teachers more positively. Around 31% of the variation in PISA scores between countries is explained by differences in Implicit Teacher Status.
- **Explicit Teacher Status:** In contrast to our findings on implicit status, the correlation between explicit views of teacher status and PISA scores is negligible. Only 3% of the variation in PISA scores between countries is explained by differences in explicitly expressed teacher status. This is a surprising result, given that one might expect explicit evaluations of teacher attributes and working conditions to be most relevant to attainment.

In addition to the above measures of teacher status, teacher wages are also strongly correlated with PISA scores. In further analyses, we determined that these effects are independent of each other. Regardless of how well teachers are paid, children perform better in countries where teacher status is higher (as measured by the ranking or implicit measures). Adjusting for teacher pay, in countries where teachers are ranked one place higher relative to other occupations, children perform 21.3 points better in PISA on average.

EXAMINING DIFFERENCES IN TEACHER STATUS ACROSS COUNTRIES

Our third objective for this report was to examine the factors that might explain cross-national differences in teacher status. This is important for two reasons.

First, as we note above, improving teacher status is, in our view, a necessary part of improving children's education worldwide.

Understanding what factors might underlie differences in teacher status is therefore an important step towards that goal. We find that teachers generally enjoy higher status in richer countries, and in countries which allot a greater fraction of public funds to education. We also find that teachers are generally lower status in countries where the profession is more feminised (i.e. where a greater fraction of the teaching workforce is female). We find that teacher status is unrelated to the extent to which schools are privately run, or to the extent to which the education system is focused on vocational training as opposed to academic education.

The second reason this analysis is important is that it also contributes to our understanding of the relationship between teacher status and student attainment. Crucially, we find that this relationship does not appear to be explained by background factors which may be related to both higher teacher status and better PISA scores (such as national wealth or government spending on education).

Finally, in addition to more concrete predictors of teacher status, we also examine potential cultural correlates. Here we find little evidence that teacher status is part of a cluster of other cultural values unrelated to education. However, we are unable to determine whether it is part of a broader sense in which education holds high intrinsic cultural value.

Adjusting for teacher pay, in countries where teachers are ranked one place higher relative to other occupations, children perform 21.3 points better in PISA on average.

DATA AND METHODOLOGY

Photo: Global Teacher Prize Finalist Anh Phuong Ha (Vietnam) © Anh Phuong Ha

DATA

This report is based principally on data from the 2018 GTSI survey. This survey, which was undertaken by the polling company Populus, included more than 41,000 people in 35 countries. The sample in each country comprised two components. First, quota sampling was used to obtain a balanced and demographically representative sample of 1,000 members of the general public in each country. Second, an additional over-sample of 200 teachers was surveyed in each country. Data were collected through a mix of online and face-to-face, computer-aided personal interviewing (CAPI). Full details of the survey methodology can be found in Dolton et al., (2018). A full copy of the questionnaire is included as an Appendix to this report. All results described in this report are based on the general population sample in each country. An additional over-sample of teachers was also surveyed, but the data from this additional sample is excluded from the following analyses.

METHODS

This report describes the results of three main sets of analyses:

MEASURING TEACHER STATUS

An examination of three alternative measures of teacher status:

- **Ranking status measure:** How teachers are ranked relative to other comparable occupations.
- **Implicit status measure:** Measuring respondents' implicit perceptions of teachers.
- **Explicit status measure:** Measuring respondents' explicit judgements about teachers.

The derivation of these measures is described in detail in the section "Teacher status: Three alternate measures".

COMPARING TEACHER STATUS AND STUDENT ATTAINMENT

An examination of the relationship between the three alternative measures of teacher status and student attainment, as measured by PISA scores. These analyses examine the relationship between:

- Average teacher status scores; and:
- Average scores in PISA Reading, Mathematics and Science at the country level from the 2018 PISA assessments.

It should be noted that five of the 35 countries participating in the GTSI 2018 survey did not take part in the PISA assessments (Egypt, Ghana, India, Taiwan and Uganda²). Our analyses are therefore based on the remaining 30 countries. Full details of this analysis are given in the section “Teacher status and student outcomes”.

EXAMINING THE FACTORS THAT DRIVE TEACHER STATUS

An examination of country-level predictors of teacher status. These analyses examine the relationship between:

- Various country-level predictors (including national wealth, education spending, the gender composition of the teaching workforce, and measures of cultural values); and
- Average teacher status.

Data sources and details of each indicator are given in the section “Teacher status across countries”.

² Due to differences in education systems, education outcomes, and teacher status, we consider Taiwan separately from the People’s Republic of China for the purposes of our analyses.

What explains why teachers are accorded so much more respect in some countries than others? And what are the implications of teacher status for students? Do students in countries where teachers are highly respected perform better?

1. TEACHER STATUS: THREE ALTERNATE MEASURES

Photo: Global Teacher Prize Finalist Samuel Isaiah (Malaysia) © Samuel Isaiah

In this investigation we explore three different methods for measuring the status of teachers: Ranked, Implicit and Explicit. In this section we explain the rationale for these three different measures and how they were computed.

RANKED TEACHER STATUS

Our first measure of teacher status is based on a ranking of occupations in relation to each other. GTSI 2018 respondents were asked to rank the following 14 professions in the order of how well they thought were respected (with 14 being the highest and 1 being the lowest):³

- Primary school teacher
- Secondary school teacher
- Head teacher
- Doctor
- Nurse
- Librarian
- Local government manager
- Social worker
- Website designer
- Police officer
- Engineer
- Lawyer
- Accountant
- Management consultant

³ The order of this list was randomised to ensure that responses were not biased by the order in which occupations were listed.

Table 1: Average status rank across all countries

(Highest=14; Lowest=1)

Occupation	Average Rank
Doctor	11.6
Lawyer	9.5
Engineer	9.1
Head teacher	8.1
Police officer	7.8
Nurse	7.4
Accountant	7.3
Local government manger	7.3
Management consultant	7.1
Secondary school teacher	7.0
Primary school teacher	6.4
Web designer	5.9
Social worker	5.8
Librarian	4.6

These occupations were deliberately chosen to require at least secondary education along with further training (which for the majority will be a degree, but for others will be professional training). The occupations were also carefully selected to cover a variety of different types of work in both the private and public sectors.

The rationale for this measure is that respondents are not required to make an explicit quantitative judgement about any specific occupation on any set dimension. Rather, the ranking measure taps into a more instinctive sense of which occupations are more or less prestigious. This is similar to the rationale for widely used CAMSIS measure of occupational status (Prandy and Jones, 2001).

The average rank for each occupation across all countries is given in Table 1.

This table shows that headteachers are, on average, ranked among the top four occupations, but that secondary and primary teachers are near the bottom, above only librarians, social workers and web designers. However, these averages disguise a high degree of heterogeneity between countries, as can be seen in Figure 1, below, which shows the average ranking accorded to each type of teacher in each of the countries participating in GTSI 2018.

Figure 1: Headteacher, secondary teacher and primary teacher occupational respect rankings by the general public across countries

Figure 1 shows some consistent patterns: headteachers were perceived as more highly respected than secondary teachers in every country except Taiwan and Hungary. Secondary teachers were perceived as more highly respected than primary teachers in every country except Turkey, the USA, and France. However, there are pronounced differences between countries in the status rank of teachers. Focusing on secondary teachers specifically, at the bottom of the scale in Brazil and Israel, they are on average ranked only fifth out of the 14 occupations. Whereas in China and Malaysia, at the other end of the scale, secondary teachers are ranked eighth or ninth.

It is these variations in teacher status (as measured by ranking measurement as well as by our implicit and explicit measurements) that we explore in this report. What explains why teachers are accorded so much more respect in some countries than others? And what are the implications of teacher status for students? Do students in countries where teachers are highly respected perform better?

IMPLICIT TEACHER STATUS

Our second measure of occupational status is an attempt to tap into respondents' implicit (unconsidered, automatic) impressions of teachers. This is measured using a sequence of word associations. Respondents were asked to, as quickly as possible, indicate which one of the following pairs of opposite words they most associated with teachers:

- **Trusted/Untrusted**
- **Well paid/Poorly paid**
- **Influential/Not influential**
- **Inspiring/Uninspiring**
- **Respected/Not respected**
- **High status/Low status**
- **Hard working/Lazy**
- **Caring/Uncaring**
- **High flyer/Mediocre**
- **Intelligent/Unintelligent**

To create our measure of Implicit Teacher Status we combined information on whether the respondent gave a positive or negative response with information on how long they took to respond. Positive responses were given a positive score, and negative responses a negative score. The value of the score depended on the time taken to respond: responses given in under two seconds were given a score of +5 or -5 (depending on whether the response was positive or negative), responses given in two to four seconds were given a score of +4/-4, responses in four to six seconds a score of +3/-3, responses in six to eight seconds a score of +2/-2, and responses between eight to 10 seconds a score of +1/-1. Responses after 10 seconds were given a score of zero. These scores were summed and then rescaled to give a score from 0-100. In this way, quicker responses were assumed to be indicative of a more decisive view.

The rationale for this measure is based on a large volume of psychological research demonstrating that people's spontaneous, unreflective feelings can be quite different to their deliberate, considered attitudes (Mayerl, 2013). In an often-studied example, spontaneous measures find evidence of negative attitudes towards ethnic minorities which are not picked up by conventional survey questions (Banaji, 2013).

Figure 2: Mean Implicit Teacher Status scores across countries

This may be a consequence of social desirability bias: when asked a conventional survey question, respondents give the answer they think will reflect best on them, rather than their true feelings (Dovidio et al., 1997). Or it may be because the negative attitudes in question are largely implicit. Implicit attitudes are unconscious, automatically activated feelings and associations we hold in relation to certain subjects or groups (Greenwald et al., 1998). For example, consciously we may genuinely believe that women are no less technically competent than men. However, due to persistent exposure to sexist stereotypes, unconsciously we may associate greater technical competence with men (Moss-Racusin et al., 2012).

The majority of the previous literature on the difference between spontaneous and deliberate attitudes has focused on negative feelings about traditionally stigmatised groups (Banaji, 2013). Teachers clearly do not fit this description. However, precisely the same processes may apply to teachers as to other groups. When asked conventional survey questions, respondents may feel a social pressure to give a positive view of teachers, even if their true feelings or beliefs are quite different. Respondents may also hold positive or negative unconscious perceptions of teachers – feelings and associations of which they themselves are not fully aware. Measures which encourage spontaneous, reflexive responses

may therefore offer an additional insight into the popular perception of teachers in the survey countries.

Figure 2 shows the average of this score across the countries in our sample.

EXPLICIT TEACHER STATUS

Our third measure of teacher status is based on participants' explicit responses to questions about the characteristics of teachers and teaching. Respondents were asked to what extent they agreed or disagreed with the following nine propositions concerning the working conditions, abilities, and professionalism of teachers:

- Being an effective teacher requires rigorous training.
- **It is too easy to become a teacher.**
- **The quality of teachers is too variable.**
- Pupils respect teachers in my country.
- The teachers in my children's school are respected by their pupils.
- Teachers work hard.
- Teachers enjoy a positive media image.
- **Teachers have long holidays.**
- Teachers have the autonomy to exercise their professional judgement.

Response options were: Strongly Agree, Tend To Agree, Neither Agree Nor Disagree, Tend To Disagree, Strongly Disagree. We scored these responses as follows:

- Strongly Agree (5)
- Tend To Agree (3)
- Neither Agree Nor Disagree (0)
- Tend To Disagree (-3)
- Strongly Disagree (-5)

The statements given in red text in the list above were considered to indicate a negative view of teachers (where the rest of the statements indicated a positive view). Responses to these statements were therefore scored in the reverse direction.

Figure 3: Mean Explicit Teacher Status scores across countries

To these nine items we added a tenth (scoring indicated in parentheses):

“Imagine you had children. To what extent do you think you would encourage or not encourage them to become a teacher?”

- **Definitely Encourage (5)**
- **Probably Encourage (3)**
- **Maybe Encourage (0)**
- **Probably Not Encourage (-3)**
- **Definitely Not Encourage (-5)**

The scores on these 10 items were summed, then rescaled to give a score from 0 to 100.

Figure 3 shows the average of this score across the countries in our sample.

Table 2: Correlations between the different measures of teacher status (Pearson's R) in the full non-teacher sample

(N=35,566)

	Rank (Primary)	Rank (Secondary)	Rank (Head)	Implicit status	Explicit status
Rank (Primary)	-	-	-	-	-
Rank (Secondary)	0.55	-	-	-	-
Rank (Head)	0.18	0.23	-	-	-
Implicit status	0.20	0.23	0.13	-	-
Explicit status	0.17	0.18	0.10	0.52	-

COMPARING THE THREE MEASURES OF TEACHER STATUS

Table 2 shows the extent of the correlation between our three measures of teacher status. Focusing first on the Ranking Measure, this table shows that the rank accorded to primary and secondary teachers is strongly correlated (0.55). People who rank secondary school teachers highly also tend to rank primary school teachers highly. However, ranking of primary and secondary school teachers is much more weakly correlated with the ranking of headteachers, suggesting that the extent to which headteachers are respected is to some extent separable from the respect accorded to the main body of the teaching profession.

Table 2 also shows that there is a strong correlation (0.52) between our implicit and explicit measures of teacher status. This suggests that, despite the differences in the way they are measured, these two measures may be capturing a common underlying concept. The correlation between these measures and the ranking measure is, however, much lower. This suggests that these two sets of measures may be capturing different elements of teacher status. It is plausible that our explicit and implicit measures are capturing respondents' evaluations (explicit and implicit, respectively) of teacher attributes and characteristics. Whereas our ranking measure focuses more strongly on prestige and respect. The distinction between these concepts is clear if we recognise that a respondent may easily consider teachers to be good at their jobs (competent, trustworthy, inspiring, well-trained, etc.) while still feeling that they are not highly respected relative to other professionals.

Table 3: Correlations between perceived teacher pay and perceived teacher status (Pearson's R) in the full non-teacher sample

(N=35,566)

	Respect (Primary)	Pay (Primary)	Respect (Secondary)	Pay (Secondary)	Respect (Head)	Pay (Head)
Respect (Primary)	-	-	-	-	-	-
Pay (Primary)	0.29	-	-	-	-	-
Respect (Secondary)	0.55	0.21	-	-	-	-
Pay (Secondary)	0.20	0.51	0.27	-	-	-
Respect (Head)	0.18	0.04	0.23	0.09	-	-
Pay (Head)	0.09	0.13	0.13	0.19	0.30	-

RELATIONSHIP BETWEEN PERCEIVED STATUS AND PERCEIVED PAY

In addition to being asked to rank teachers in terms of their perceived status, GTSI 2018 respondents were also asked to rank them against the same professions in terms of their perceived pay. It is possible that people's answers to these questions may influence each other. For example, respondents who rank teachers highly in terms of perceived respect may feel obligated, through a sense of consistency, to rank them highly in terms of perceived pay as well. To account for this possibility, a random half of the sample was asked the pay question before the respect question, and vice-versa.

Table 3 shows the correlations between the pay and respect questions for the full sample. This table re-affirms the disconnection between primary and secondary teachers on the one hand and headteachers on the other. The perceived pay of primary teachers is highly correlated with the perceived pay of secondary teachers, but the pay perceptions of both of these groups are only weakly correlated with the perceived pay of headteachers.

Table 3 also shows that there is only a moderate correlation between perceived pay and perceived respect for the three groups of teachers. This suggests perceptions of pay and respect are not strongly connected.

Respondents recognise that while teachers may be highly respected, they may not be highly paid (or vice-versa).

We proceeded to repeat the same analysis separately for those respondents who answered the pay question first and for those who answered the respect question first. Our results show that the correlations are consistently higher among respondents who were asked the respect question first. This suggests that first asking respondents to consider the extent that teachers are respected encourages them to bring their responses on pay more closely in line with their respect ranking.

People who rank secondary school teachers highly also tend to rank primary school teachers highly. However, ranking of primary and secondary school teachers is much more weakly correlated with the ranking of headteachers.

2. TEACHER STATUS AND STUDENT OUTCOMES

Photo: Global Teacher Prize Finalist Antonio Pérez Moreno (Spain)

© Antonio Pérez Moreno

In the GTSI 2018 report, we examined the relationship between our combined GTSI measure and the most recent PISA scores that were available at the time of writing (PISA 2015). Since that report was published, PISA scores from the tests pupils sat in 2018 have become available. These are much more directly relevant to measures in the GTSI 2018 survey, which was conducted in the same year. In this report we therefore update our previous analysis of the relationship between teacher status and student outcomes as measured by PISA scores. Here we also expand on our previous analysis by comparing the predictive power of our three alternative measures of teacher status. Based on our previous results, we expect that countries where teachers enjoy higher status will also have better student attainment.

CREATING THE GTSI SCORE

The GTSI score was created using Principal Component Analysis (PCA). Through PCA, we examine the correlation between people's responses to a variety of different survey questions, and accordingly determine whether these can be explained by a smaller number of underlying factors.

We applied a PCA model to the following four questions that were asked in the GTSI survey:

1. Ranking primary school teachers against other professions.
2. Ranking secondary school teachers against other professions.
3. Ranking of teachers according to their relative status based on the most similar comparative profession.
4. Perceived pupil respect for teachers.

The PCA reduced these four factors to a single fundamental measure of teacher status, which we re-scaled to produce a 0-100 score representing the status of teachers in each country. Full details of the statistical methodology and construction of the index may be found in the technical appendices of the GTSI 2018 report.

Figure 4: Scatterplot of country mean GTSI 2018 score against PISA 2018 scores

TEACHER STATUS AND PISA SCORES: THE RELATIONSHIP

Figure 4 replicates our primary analysis from the GTSI 2018 report by plotting each country's average GTSI 2018 score against its PISA 2018 score. The overall PISA score given in these figures is the mean average of each country's absolute scores in Reading, Science, and Mathematics. The GTSI 2018 score represents our attempt to compile a single, global measure of teacher status for each country. It is not one of the three alternative measures of status we focus on in this report, but is included as an update of our findings as reported in the main GTSI 2018 report.

Figure 4 shows that there is a positive relationship between the 2018 GTSI and PISA scores. Countries in which our global measure indicates that teachers enjoy high status also tend to do better in the PISA assessments. However, this relationship is not particularly strong: The correlation coefficient is 0.28, indicating a moderate correlation. The R squared statistic reported on the chart is 0.08, indicating that around 8% of the variation in PISA scores between countries is explained by differences in teacher status as measured by GTSI 2018.

Figures 5-7 show the same relationship between teacher status and PISA scores, but for each of our three measures of teacher status separately. For the ranking measure, we focus on secondary teachers specifically as PISA tests are administered to secondary school age students (aged 15).

Figure 5: Scatterplot of mean secondary teacher respect rank against PISA 2018

Figure 6: Scatterplot of mean Implicit Teacher Status score against PISA 2018

Figure 7: Scatterplot of mean Explicit Teacher Status score against PISA 2018

Figure 8: Scatterplot of mean annual secondary school teacher wage against PISA 2018

Figures 5-7 show that, of the three teacher status measures, Implicit Teacher Status scores are the strongest predictor of PISA outcomes. The correlation between Implicit Teacher Status scores and PISA outcomes is remarkably strong (a correlation coefficient of 0.55), with the R-squared value showing that almost a third (0.31) of the variation in PISA scores can be explained by this measurement of teacher status. There is also a moderately strong correlation (a correlation coefficient of 0.36, an R-squared of 0.13) between Ranked Teacher Status and PISA scores. The relationship between our Explicit Teacher Status measure and PISA scores is considerably weaker (a correlation coefficient of 0.17, an R-squared of 0.03). From these results, it appears that the extent to which teachers are implicitly respected and admired is considerably more important for student outcomes than explicit evaluations of teacher quality and working conditions. This is a surprising finding, given that one might expect evaluations of teacher quality and working conditions to have a closer relationship with PISA scores, which are often considered to be an indicator of the quality of teaching and support students receive.

For the purposes of comparison, Figure 8 shows the relationship between PISA scores and the amount that secondary school teachers are paid in equivalent USD.⁴ This figure shows that teacher wages are a strong predictor of PISA scores. However, notably, they are not as strongly related to PISA scores as our measure of Implicit Teacher Status.

The analyses reported above examine only the straightforward, bivariate relationship between teacher status and pay and PISA scores. By contrast, Table 4 shows the results of a series of linear regression models predicting PISA 2018 scores from each of our measures of teacher status (and from perceived teacher pay rank) while holding constant average teacher wages. This table shows a clear relationship between the respect ranking of teachers and PISA scores: Countries in which secondary school teachers are ranked one place higher score 21.3 points better in PISA on average. By contrast, the perceived pay of teachers does not strongly predict PISA scores.

⁴ See the technical appendices to the GTSI 2018 report for a full explanation of how teacher pay was derived.

Table 4. Regression analysis of PISA 2018 scores on status score alternatives

	(1)	(2)	(3)	(4)	(5)
	Respect rank	Pay rank	Implicit score	Explicit score	GTSI2018
Teacher wage	0.00152*** (3.24)	0.00170*** (3.11)	0.00106** (2.15)	0.00156*** (3.12)	0.00164*** (3.46)
Respect rank	21.28** (2.24)	26.12** (2.16)			
Pay rank		-9.483 (-0.66)			
Implicit score			2.082** (2.66)		
Explicit score				2.178 (1.04)	
GTSI2018					0.779** (2.12)
Constant	279.7*** (4.13)	295.3*** (4.08)	327.0*** (8.04)	310.7** (2.76)	392.4*** (17.11)
Observations	30	30	30	30	30
R2	0.374	0.384	0.411	0.286	0.364

t statistics in parentheses

* p < 0.10, ** p < 0.05, *** p < 0.01

Matching the results reported in Figure 6, above, our Implicit Teacher Status measure also strongly predicts PISA scores, even after accounting for teacher wages: Countries where the Implicit Teacher Status score is 10 points higher (on our scale of 0-100) would be predicted to score 20.8 points higher on the PISA assessments. Also reflecting the above results, our Explicit Teacher Status score is not strongly predictive of PISA scores.

In addition to these findings, we also found that our existing GTSI 2018 score was a significant determinant of PISA attainment. This is an important result as it mirrors our findings from the 2013 and 2018 GTSI reports. This is notable because it shows that the relationship between teacher status and PISA scores remains robust over two different surveys of teacher status (GTSI 2013 and GTSI 2015) and three different PISA rounds.

3. TEACHER STATUS ACROSS COUNTRIES

Photo: The class of Global Teacher Prize Finalist Leah Juelke (USA) © Leah Juelke

Why do teachers enjoy considerably higher or lower status in some countries than others? This is an important question in terms of determining what might be done to improve teacher status in countries where it is currently low. It is also important in terms of our efforts to understand how teacher status might affect student outcomes (particularly PISA scores). If some other factor (for example, education spending), strongly predicts teacher status and PISA scores, then perhaps it is this fact that explains why status scores and PISA attainment are linked, rather than a causal effect of teacher status.

There is a moderate correlation between what a country spends on education and the status of teachers in that country

TEACHER STATUS AND EDUCATIONAL INDICATORS

In this section, we examine the relationship between teacher status and a variety of important education indicators. Because our previous analyses showed that our measure of implicit status was most closely associated with PISA, we focus on this measure for these analyses.

Unless otherwise stated, all educational indicators are taken from the World Bank Education Statistics database (EdStats) for the year 2018 or the most recent available previous year.

We begin by examining the relationship between teacher status and indicators of national wealth and education spending. It is plausible that teachers would enjoy higher status in richer countries that spend more on education. Figures 9 and 10 show that this is indeed the case, though the correlation in both cases is only moderate.

Figure 11. Scatterplot of mean Implicit Teacher Status against the proportion of secondary school pupils who are enrolled in privately run schools

Figure 12. Scatterplot of mean implicit teacher status against the proportion of secondary school pupils enrolled in vocational programmes

Figure 13. Scatterplot of mean Implicit Teacher Status against the proportion of secondary school teachers who are female

In addition to national wealth and spending, the composition of the education system itself may affect the status of teachers. For example, teachers may be evaluated differently in education systems that are strongly dominated by the private rather than the public sector. Figure 11 plots the relationship between teacher status and the proportion of secondary school pupils who are enrolled in privately run institutions.⁵ This shows that there is in fact no relationship between teacher status and the extent to which secondary schools are privately versus publicly run.

In terms of pupil characteristics, we also hypothesised that teachers may enjoy lower status in countries where the secondary education system is more strongly focused on vocational education. However, Figure 12 also shows that teacher status is not related to the fraction of secondary school students enrolled in vocational (as opposed to academic) programmes.

Finally, we hypothesised that, due to sexist attitudes, teachers may enjoy lower status in countries where the profession is more strongly dominated by women. Figure 13 shows that there is indeed a moderate negative

⁵ Note that schools which depend on government funding but are otherwise managed by private institutions (such as academy schools in England) are considered “privately run institutions” for the purposes of calculating this figure.

correlation between teacher status and the proportion of secondary school teachers who are female.⁶

These results show that there are a number of factors which may be important predictors of Implicit Teacher Status, including national wealth, spending on education, and the gender composition of the teaching workforce. If these factors are also predictors of PISA attainment, they may therefore at least partly explain the link between the social status of teachers and performance in international standardised testing.

Implicitly held beliefs about teachers are affected by national wealth, spending on education and the gender composition of the teaching workforce.

To account for this possibility, we first examined the relationship between each indicator and PISA scores. This showed that only GDP had a positive relationship with both teacher status and PISA scores. A subsequent linear regression model demonstrated that the relationship between Implicit Teacher Status and PISA scores was robust to adjustment for GDP per capita. As we show in the previous section, the association between Implicit Teacher Status and PISA scores is also not explained by teachers being paid more in countries where they are accorded higher status.

⁶ In this figure, data for Japan, Canada, and Israel are taken from the OECD Education at a Glance database. For Canada, the figure for 'Upper Secondary' is taken to represent secondary education as a whole.

Table 5. Ranking countries by our three measures of teacher status

TEACHER STATUS AND CULTURAL VALUES

In this section we take a different approach to examining cross-national variation in teacher status. Table 5 ranks all of the countries in the dataset by their scores on our three alternate measures of teacher status. A simple way to read this table is to pick a specific country and examine its rank in each ordering. For example, consider China. Reading across the columns we see that China is ranked in the top three for all of our status measures. By contrast, Israel is in the bottom four for all three measures.

Doing this repeatedly for each country we can see that there is a high degree of concordance between the rankings (as would be suggested by the high degree of correlation we observed in a previous section).

Teacher status tends to be similar between countries on the same continent, and is generally highest in Asian countries and lowest in South American countries.

A notable facet of this table is that countries on the same continent tend to be grouped together. This is particularly clear for the Asian countries (marked in red), which consistently appear near the top of the table. It is also apparent that the South American countries (marked in green) often (though slightly less consistently) appear in the bottom half of the table. This geographical clustering suggests that there may be common cultural factors which explain differences in teacher status. This is of course not to suggest that all Asian or South American countries share a common culture, but merely that countries which are closer together geographically also tend to be more similar in terms of cultural exchanges, languages and a shared history.

We explored this possibility by examining the association between teacher status and a variety of cultural values captured by the 2010-2014 World Values Survey (the most recently collected data).⁷ We found that, in general, Implicit Teacher Status was not closely correlated with indicators of individualism (the extent to which people in the country valued personal wealth and achievement versus helping others) or with the proportion of a

⁷ Full details of the variables used in this analysis are given in the Technical Appendix.

country's population who felt that obedience versus self-expression was a quality that should be encouraged in children. However, we found that Implicit Teacher Status was moderately negatively correlated (a correlation coefficient of -0.34) with an indicator of the extent of respect for authority (the proportion of the population who believed that "greater respect for authority" would be a positive development). This suggests that in countries where respect for authority is more highly valued, teacher status is lower.⁸ Although there is the odd exception these results were broadly consistent for our other two measures of teacher status (explicit and ranking).

Teacher status may be strongly determined by culture – it may be part of a broader cluster of beliefs and attitudes concerning the value of education.

Based on the geographical clustering of teacher status, our analysis suggests that teacher status may be strongly culturally determined. However, it does not appear to be strongly predicted by other plausibly related cultural values such as individualism. Instead, it is possible that teacher status is part of a broader cluster of attitudes and beliefs concerning the value of education.

⁸ This correlation is only moderate so there are a number of exceptions, for example China.

SUMMARY AND CONCLUSIONS

Photo: Global Teacher Prize Finalist Lilia Melo (Brazil) © Lilia Melo

In this report we introduced and examined three different definitions and measures of teacher status. These measures were based on:

- **Ranked Teacher Status:** How people ranked teachers relative to other occupations in terms of respect;
- **Implicit Teacher Status:** How people responded to quick-fire word association tests assessing implicit perceptions of teachers; and
- **Explicit Teacher Status:** How people responded to a series of explicit questions concerning teachers' attributes and working conditions (including their level of training, overall quality and professional judgement).

We found that, although these measures were related, and all in some sense captured “teacher status”, they were nevertheless quite distinct. Implicit and explicit perceptions of teachers were highly correlated, but both were less strongly correlated with the ranking measure. Given the content of the implicit word associations and explicit questions, it seems likely that these two measures offer an insight into respondents' evaluations of teacher attributes – particularly teacher quality.

There is a clear relationship between teacher status and student outcomes as measured by PISA scores.

By contrast, the ranking measure more directly assesses respondents' instinctive sense for how much respect or prestige is accorded to teachers in their country. It is apparent from these results that respondents are fully able to separate their perceptions of how much teachers are respected by society in general from their own attitudes towards teachers (and particularly their sense of teacher quality). We should note here that, although our Implicit and Explicit Teacher Status Measures were highly correlated, they were far from perfectly so. This suggests that, despite their overlap in content, these measures are offering two different windows into people's perceptions of teachers. This distinction is important for our analysis of the relationship between teacher status and student attainment, as we describe below.

In our previous reports (in 2013 and 2018), we observed a clear relationship between teacher status (as measured by our principal measure of teacher status, the GTSI 2018) and student outcomes as measured by PISA scores. In this report, we are able to re-affirm this

finding with the newly released 2018 PISA data. This is a particularly important result as it demonstrates that the relationship between teacher status and student attainment is robust across entirely separate datasets collected from a different cohort in each country five years apart and surveyed over many more countries. This substantially increases the likelihood that this result reflects a genuine relationship between teacher status and student attainment at the national level.

In this report, we explored the relationship between teacher status and student attainment by examining it using our three alternative measures of teacher status separately. We found a substantial link between the ranking measure and PISA scores, echoing our finding with the overall GTSI 2018 measure. However, we found an even more striking correlation between our implicit measure of teacher status and PISA scores. This analysis showed that almost a third (31%) of the variation in PISA scores between countries could be explained by this measure alone. This association (and the association between the ranking measure and PISA scores) was robust to controlling for actual teacher wages in each country (at purchasing power parity). This suggests that, alongside teacher pay, teacher status is a crucial determinant of student attainment.

Almost a third of the variation in PISA scores between countries could be explained by Implicit Teacher Status – by people’s implicitly held views about teachers.

In contrast with the implicit and ranking measures, our explicit measure of teacher status was not a substantive predictor of PISA scores. This difference between the measures suggests that people’s explicit evaluations of (for example) teacher quality are less relevant for student outcomes than their implicit perceptions of teachers and of the prestige that teaching attracts. This is surprising as one might expect explicit, considered evaluations to play a stronger role than “gut instinct” unconsidered perceptions. However, considered opinions are more strongly vulnerable to reporting bias than unconsidered, automatic responses. Our unconsidered measures may therefore offer a truer picture of people’s instinctive perception of teachers and teaching, and it is

this perception that is more strongly representative of how teachers are actually treated in the societies we analyse.

Given the apparent importance of teacher status for student attainment, we also focused in this report on predictors of teacher status. What factors explain why teachers enjoy substantially higher status in some countries than others? We found, perhaps unsurprisingly, that teachers enjoyed higher status in richer countries (as measured by GDP per capita) and in countries in which the government spent a higher fraction of its budget on education. However, we also found that teachers were held in lower esteem in countries where the teaching workforce was more strongly dominated by women. This is a dispiriting finding that suggests a level of possible gender stereotyping or societal sexism that may damage teacher status in countries where the profession is more female dominated. This is in line with previous research suggesting that the status and pay of occupations tends to drop as they become more female dominated (Levanon, England and Allison, 2009). In terms of educational policy indicators which have been suggested to increase or decrease teacher status, we found that teacher status was related neither to the extent to which schools are run by the private sector, nor to the extent to which the education system is geared towards vocational training as opposed to academics.

Geographically and culturally proximate countries tend to score similarly on teacher status in a way that does not appear to be explained by other background factors.

It should be noted that the fact that teachers enjoy higher status in richer countries which spend more on education offers a potential alternative explanation for the link we observe between teacher status and PISA scores. For example, it is possible that countries in which teachers are accorded high status do well on PISA scores not because the status of teachers is higher but because they are richer and therefore can invest more personal and public resources in increasing attainment. However, our analysis shows that the relationship between government education spending (as a proportion of total spending) and PISA scores is in fact negative, and that the relationship between teacher status and PISA scores is robust to accounting for GDP.

Although national wealth, education spending, and the gender composition of the teaching profession may be important in explaining national differences in teacher status, our analysis also suggests that cultural differences may also play a crucial role. Geographically and culturally proximate countries tend to score similarly on teacher status in a way that does not appear to be explained by other background factors. Our analysis of cultural correlates of teacher status provides little evidence that high teacher status is part of a cluster of other non-education related values (such as individualism). However, we were unable to examine the relationship between teacher status and other attitudes relating to education.

Previous research (for example, Merriman and Nicoletti, 2007; Pelham, Crabtree and Nyiri, 2009) has argued for cultural differences in the intrinsic value placed on education. For example, this may include the extent to which “doing well in school” – i.e. high educational attainment – is considered an important goal for children and young people. It seems highly likely that this – the cultural value placed on education – may be an important predictor of the status of teachers. However, to our knowledge, there are no international survey data that provide information on the value of education across different cultures. Future survey research on this topic would be highly valuable.

In summary, this report has shown that:

- There are large differences in the status of teachers between countries.
- The global concept of “teacher status” can be decomposed and measured in different ways.
- The distinction between these ways of capturing teacher status has important implications for the relationship between teacher status and student attainment.
- Measures which tap into people’s unconsidered, automatic perceptions of teachers may be more genuinely reflective of the way in which teachers are treated in society – with this treatment being the most crucial for student outcomes.
- A country’s student attainment (as measured by PISA scores) is strongly related to the status of teachers (in particular when measured implicitly), and that this relationship is not explained by differences in national wealth or actual teacher pay. A clear corollary here is that a greater focus should be placed on raising the status of teachers across the world.
- That teacher status is related to national wealth, education spending, and the gender composition of the teaching workforce, but is not directly related to clear policy differences such as the role of the private sector in providing education or the extent to which the education system is geared towards vocational programmes.
- That teacher status is likely to be partly culturally determined, although it remains an open question as to whether high teacher status is part of a broader set of attitudes relating to the intrinsic value of education.

TECHNICAL APPENDIX

WORLD VALUES SURVEY ANALYSIS

For our analysis of cultural correlates of teacher status we used data on cultural values from the most recent World Values Survey (WVS), for which data was collected over the period 2010-2014. Of the countries participating in the 2010-2014 WVS, 20 also participated in the GTSI 2018 survey: Argentina, Brazil, Chile, China, Colombia, Egypt, Germany, Ghana, India, Japan, Malaysia, Netherlands, New Zealand, Peru, Russia, Singapore, Spain, Taiwan, Turkey, and the United States of America. Our analyses therefore apply only to these countries.

We examined the relationship between teacher status and the following four indicators derived from the 2010-2014 World Values Survey:

INDIVIDUALISM

We derived a scale for individualism by combining data from three items in the Schwartz Human Values inventory. In completing this inventory, respondents are given a list of attributes for a hypothetical person. They are asked to indicate whether this attribute is like them, using a scale from one (“very much like me”) to six (“not like me at all”). To compute an individualism scale we calculated the mean average score across the following three items (asterisks indicate items where the coding was reversed). Higher numbers indicate greater individualism:

It is important to this person to be rich; to have a lot of money and expensive things;*

It is important to this person to have a “good time” and to “spoil” oneself;*

It is important for this person to do something for the good of society.

VALUE OF OBEDIENCE VS. SELF-EXPRESSION IN CHILDREN

WVS respondents were shown a list of 11 “qualities that children can be encouraged to learn at home”. They were asked to choose up to five that they considered to be especially important.

We measured the value of obedience and self-expression at the country level by calculating the proportion of respondents in each country who chose these as important qualities from the list.

RESPECT FOR AUTHORITY

WVS respondents were asked about changes that might take place in the near future and whether they would think these changes would be a good thing, a bad thing, or that they wouldn’t mind. We measured respect for authority by the proportion of respondents who responded that “Greater respect for authority” would be a good thing.

Q18. Imagine the government of your country proposed extra taxes on the citizens of your country in order to spend 10% more of the state's money on something. Which of the below would your HIGHEST PRIORITY and LOWEST PRIORITY your government to spend the money on?

[10 OPTIONS DISPLAYED ACROSS SEVERAL SCREENS, WITH RESPONDENTS CHOOSING HIGHEST AND LOWEST PRIORITY OPTIONS. AFTER EACH SCREEN AN ANCHOR QUESTION (Q18A) WILL BE ASKED TO PROVIDE ABSOLUTE APPEAL ON THE MEASURES]

[BATTERY OPTIONS]

Reducing class size in Primary schools (pupils aged 8-11 years)

Reducing class size in Secondary schools (pupils aged 12-18 years)

Employing more teachers

Higher salaries for existing teachers

Better training and professional development for teachers

Improving school buildings and computers

Employing more non-teaching staff in schools (e.g. counsellor, pastoral staff etc.)

Do not spend it on education but instead spend it on something else (e.g. healthcare)

Do not spend any extra money and keep taxes the same

ASK ALL

Q18a. Considering all the options listed above, do you think:

[SINGLE CHOICE]

All of them are high priority

Some of them are high priority

None of them are high priority

ASK ALL

Q19 Government should redistribute income from the better off to those who are less well off.

☐ strongly disagree ☐ disagree ☐ neutral ☐ agree ☐ strongly agree

ASK ALL

Q20 Ordinary working people do not get their fair share of the nation's wealth.

☐ strongly disagree ☐ disagree ☐ neutral ☐ agree ☐ strongly agree
